Lecture 11 – Interval Scheduling
Reading: KT Section 4.1 and 4.2

Partial content of these slides have been obtained from the official lecture slides that accompany the textbook. A complete set of slides can be found at: http://www.cs.princeton.edu/~wayne/kleinberg-tardos/

Greedy analysis strategies
- Greedy algorithm stays ahead. • Show that after each step of the greedy algorithm, its solution is at least as good as any optimal algorithm’s.
- Exchange argument. • Gradually transform any solution to the one found by the greedy algorithm without hurting its quality.
- Structural. • Discover a simple “structural” bound asserting that every possible solution must have a certain value. Then show that your algorithm always achieves this bound.

Interval Scheduling
The step-by-step approach

**Earliest-Finish-Time-First \((n, s_1, s_2, \ldots, s_n, f_1, f_2, \ldots, f_n)\)**
- **Sort** jobs by finish time so that \(f_1 \leq f_2 \leq \ldots \leq f_n\)
- \(A \leftarrow \emptyset\) set of jobs selected
- **For** \(j = 1\) **to** \(n\)
  - **If** job \(j\) is compatible with \(A\)
    - \(A \leftarrow A \cup \{ j \}\)
- **Return** \(A\)

Let’s analyze!
Let’s analyze it ...

**Correctness – Step-by-step approach**
- A is a compatible set of requests
- For all indices \( r \leq k \) we have \( f(i_r) \leq f(j_r) \).
- The greedy algorithm returns an optimal set \( A \)

**Running time**
- \( O(n \log n) \)

---

**Scheduling to minimize lateness**

*Setting:*
- A single resource
- Each job \( j \) requires \( t_j \) time units, and a deadline of \( d_j \)
- \( j \) starts at \( s_j \), and is done at \( f_j = s_j + t_j \)
- The lateness of a job \( j \) is \( l_j = f_j - d_j \)

*Goal:*
- Decide on the start time of each job to minimize the maximum lateness (\( L \))
- \( L = \max_j l_j \)

---

**Greedy algorithms to minimize lateness**

- How would you order the jobs in the schedule?
Earliest deadline first

Correctness – Exchange approach

**What is it?**
- We start with an optimal solution \( O \) and turn it into the greedy solution \( A \)

**For the earliest deadline first algorithm**
- There exists an optimal schedule with no idle time
- The earliest-deadline-first schedule has no idle time
- The earliest-deadline-first schedule has no inversions
- All schedules with no inversions and no idle time have the same maximum lateness
- If a schedule (with no idle time) has an inversion, it has one with a pair of inverted jobs scheduled consecutively
- Swapping two adjacent, inverted jobs reduces the number of inversions by one and does not increase the max lateness

There is an optimal schedule that has no inversions and no idle time.

The schedule \( A \) produced by the greedy algorithm has optimal maximum lateness \( L \).
