Lecture 3 – Asymptotic Notation

Reading: KT Sections 2.1 and 2.2

Partial content of these slides have been obtained from the official lecture slides that accompany the textbook. A complete set of slides can be found at: http://www.cs.princeton.edu/~wayne/kleinberg-tardos/

Agenda

2. ALGORITHM ANALYSIS
   - computational tractability
   - asymptotic order of growth
   - survey of common running times
Algorithm efficiency

- What makes us say that an algorithm is efficient?
  - Real answer: when it’s better than its brute force counter-part

**Brute force.** For many nontrivial problems, there is a natural brute-force search algorithm that checks every possible solution.
  - Typically takes $2^n$ time or worse for inputs of size $n$.
  - Unacceptable in practice.

Polynomial time algorithms

We say that an algorithm is **efficient** if it has a polynomial running time.

**Justification.** It really works in practice!
  - In practice, the poly-time algorithms that people develop have low constants and low exponents.
  - Breaking through the exponential barrier of brute force typically exposes some crucial structure of the problem.
Worst case analysis

**Worst case.** Running time guarantee for any input of size \( n \).
- Generally captures efficiency in practice.
- Draconian view, but hard to find effective alternative.

**Exceptions.** Some exponential-time algorithms are used widely in practice because the worst-case instances seem to be rare.

Other types of analyses

**Worst case.** Running time guarantee for any input of size \( n \).

**Ex.** Heapsort requires at most \( 2n \log_2 n \) compares to sort \( n \) elements.

</table>

Table 2.1 The running times (rounded up) of different algorithms on inputs of increasing size, for a processor performing a million high-level instructions per second. In cases where the running time exceeds $10^{20}$ years, we simply record the algorithm as taking a very long time.
Big-Oh notation

**Upper bounds.** \( T(n) \) is \( O(f(n)) \) if there exist constants \( c > 0 \) and \( n_0 \geq 0 \) such that \( T(n) \leq c \cdot f(n) \) for all \( n \geq n_0 \).

- This means that \( T(n) \) grows no faster than \( f(n) \).
- For example, let’s consider \( 17n^2 \) and \( n^2 \)

Can you find \( c \) and \( n_0 \)?
Common mistakes

Equals sign. $O(f(n))$ is a set of functions, but computer scientists often write $T(n) = O(f(n))$ instead of $T(n) \in O(f(n))$.

Ex. Consider $f(n) = 5n^3$ and $g(n) = 3n^2$.
   - We have $f(n) = O(n^3) = g(n)$.
   - Thus, $f(n) = g(n)$. ✗

Big-Omega notation

Lower bounds. $T(n)$ is $\Omega(f(n))$ if there exist constants $c > 0$ and $n_0 \geq 0$ such that $T(n) \geq c \cdot f(n)$ for all $n \geq n_0$.

Typical usage. Any compare-based sorting algorithm requires $\Omega(n \log n)$ comparisons in the worst case.

Meaningless statement. Any compare-based sorting algorithm requires at least $O(n \log n)$ comparisons in the worst case.
Big-Theta notation

**Tight bounds.** $T(n)$ is $\Theta(f(n))$ if there exist constants $c_1 > 0$, $c_2 > 0$, and $n_0 \geq 0$ such that $c_1 \cdot f(n) \leq T(n) \leq c_2 \cdot f(n)$ for all $n \geq n_0$.

**Ex.** $T(n) = 32n^3 + 17n + 1$.

**Typical usage.** Mergesort makes $\Theta(n \log n)$ compares to sort $n$ elements.

Some properties to know...

**Polynomials.** Let $T(n) = a_0 + a_1 n + \ldots + a_d n^d$ with $a_d > 0$. Then, $T(n)$ is $\Theta(n^d)$.

**Pf.**

$$
\lim_{{n \to \infty}} \frac{a_0 + a_1 n + \ldots + a_d n^d}{n^d} = a_d > 0
$$
Agenda

2. ALGORITHM ANALYSIS

- computational tractability
- asymptotic order of growth
- survey of common running times

Can you think of a?

- Linear time algorithm
- Sublinear time algorithm
- Linearithmic time algorithm
- Quadratic time algorithm
- Cubic time algorithm
