TYPE CHECKING

3.1 Well-Typedness

A HOFLEMT expression \( E \) is said to be well-typed if it is possible to prove that it has a type \( T \) using a set of typing rules. It turns out that HOFLEMT satisfies a type soundness theorem:

\[
\text{for any well-typed HOFLEMT expression } E \text{ that has a type } T, \text{ the run-type value of } E \text{ is guaranteed to be a member of the set of values denoted by } T.
\]

The type soundness theorem means that it is impossible to encounter a type error when evaluating a well-typed expression at run-time. The type soundness theorem is often summed up by the motto "Well-typed programs do not go wrong". This motto is somewhat deceptive -- well-typed programs can encounter errors at run-time, but those errors cannot be type errors. Other errors that can still be encountered are errors that depend on particular values (e.g. divide-by-zero, attempt to take the head of an empty list, accessing an array at an out-of-bounds index) as well as logical errors in the program (it gives the wrong answer).

We use the notation \( E : T \) to indicate that \( E \) is a well-typed expression with type \( T \). For example:

\[
() : \text{unit} \\
\text{true} : \text{bool} \\
5 : \text{int} \\
"foo" : \text{string} \\
\text{(symbol cs251)} : \text{sym} \\
\text{(prepend 42 (prepend -17 (empty int)))} : \text{(listof int)} \\
\text{(abs ((a \text{ int}) (b \text{ int})) (div (+ a b) 2))} : \text{(-} \text{(int int)} \text{ bool)}
\]

Type environments are environments that associate value variable names with types. We will write type environments as sets of bindings of the form \( E : T \). For example, the type environment \( \{a: \text{int}, b: \text{bool}, f: \text{(-} \text{(int)} \text{ int)}\} \) associates the name \( a \) with the type \( \text{int} \), the name \( b \) with the type \( \text{bool} \), and the name \( f \) with the type \( \text{(-} \text{(int)} \text{ int)} \). If \( A \) is a type environment, \( I \) is an identifier, and \( T \) is a type, we use the notation \( A(I) \) to denote the type bound to \( I \) in type environment \( A \), and \( A+\{I_1 : T_1, \ldots, I_n : T_n\} \) to stand for the environment \( A \) extended with bindings between \( I_1 \ldots I_n \) and \( T_1 \ldots T_n \), respectively.

Just as expressions can be evaluated relative to a value environment, expressions can be typed relative to a type environment. A type judgement of the form \( A \vdash E : T \) is pronounced "Given the type environment \( A \), \( E \) has type \( T \)" or, more succinctly, "\( A \) proves that \( E \) has type \( T \).

3.2 Proving Expressions Well-Typed

The well-typedness of expressions can be formalized in terms of a set of typing rules. A typing rule has the form

\[
\text{(rule name)} \quad \frac{\text{Hypothesis}_1; \ldots; \text{Hypothesis}_n}{\text{Conclusion}}
\]

where each of the hypotheses and conclusions is a typing judgement. Such a rule is pronounced as follows: "If the hypotheses \( \text{Hypothesis}_1 \ldots \text{Hypothesis}_n \) are all true, then the conclusion \( \text{Conclusion} \) is true." The name \( \text{rule name} \) is just a handy way to refer to a particular rule.
The typing rules for HOFLEMT appear in Figure 2. These rules use the following metavariable conventions:

- $A$ ranges over type environments
- $N$ ranges over numeric literals
- $E$ ranges over expressions
- $I$ ranges over identifiers
- $T$ ranges over types

The typing rules in Figure 2 can be used to prove that a given HOFLEMT expression is well-typed. A proof that expression $E$ is well-typed with respect to a type environment $A$ is a tree of type judgements where:

- The root of the tree is $A \vdash E : T$ for some type $T$;
- Each judgement $J$ appearing in the tree is justified by instantiating one of the typing rules such that $J$ is the conclusion of the instantiated rule and the children judgements of $J$ are the hypotheses of the instantiated rule.

Such a tree of judgements whose root is the judgement $J$ is said to be a type derivation (or typing) for $J$.

For example, consider the expression

$$(\text{bind} \; \text{app5} \; (\text{abs} \; ((f \to (\text{int}) \text{ bool}))) \; (f \; 5)) \; (\text{app5} \; (\text{abs} \; ((x \; \text{int})) \; (> \; x \; 0)))$$

Suppose that we want to show that this expression is well-typed with respect to the empty environment. Because the typing derivation will be a rather wide tree, we will introduce the following abbreviations to make it narrower:

- $T_{IB} = (\to (\text{int}) \text{ bool})$
- $T_{IBB} = (\to (T_{IB}) \text{ bool})$
- $E_{absf} = (\text{abs} \; ((f \; T_{IB})) \; (f \; 5))$
- $E_{absx} = (\text{abs} \; ((x \; \text{int})) \; (> \; x \; 0))$
- $E_{bind} = (\text{bind} \; \text{app5} \; E_{absf} \; (\text{app5} \; E_{absx}))$
- $A_1 = \{ f : T_{IB} \}$
- $A_2 = \{ \text{app5} : T_{IBB} \}$
- $A_3 = \{ \text{app5} : T_{IBB}, x : \text{int} \}$

Below is a typing derivation for the expression that proves that it has type $\text{bool}$. Each horizontal line is labeled with the name of the instantiated rule. Note that the leaves of the typing derivation are judgements involving literals or variables; these have no hypotheses. Also note that the “shape” of the derivation is an “upside down” abstract syntax tree for the expression at the root. That is, a judgement for an expression $E$ follows from the judgements of its direct subexpressions.

\[
\begin{align*}
&\text{((var)} A_1 |- f : T_{IB} ; (\text{int}) A_1 |- 5 : \text{int} ; \\
&\text{(app)} A_2 |- \text{app5} : T_{IBB} ; (\text{abs}) A_2 |- (\text{abs} ((x \; \text{int})) (> \; x \; 0)) : T_{IB} \\
&\text{(bind)} A_3 |- (\text{bind} \; \text{app5} \; E_{absf} \; (\text{app5} \; E_{absx})): \text{bool}
\end{align*}
\]
\[
\begin{align*}
(\text{int}) & \quad A \vdash -N : \text{int} \quad \text{(Other literal rules are similar)} \\
(\text{var}) & \quad A \vdash I : A(I) \\
& \quad A \vdash -E_1 : \text{bool}; A \vdash -E_2 : T; A \vdash -E_3 : T \\
(\text{if}) & \quad A \vdash \text{(if } E_1 \text{ } E_2 \text{ } E_3 : T) \\
(\text{abs}) & \quad A \vdash \text{(abs } (I_1 : T_1, \ldots, I_n : T_n) : T \\
& \quad A \vdash -E_0 : (\rightarrow (T_1 \ldots T_n) : T) \\
(\text{app}) & \quad A \vdash -E_1 : T_1; \ldots; A \vdash -E_n : T_n \\
& \quad A \vdash \text{(app } E_1 \ldots E_n : T) \\
(\text{bindpar}) & \quad A \vdash \text{(bindpar } (I_1 : T_1, \ldots, I_n : T_n) : T \\
& \quad A \vdash \text{where } \text{A}_{\text{rec}} = A + \{I_1 : T_1, \ldots, I_n : T_n\} \\
(\text{bindrec}) & \quad A \vdash \text{(bindrec } (I_1 : T_1, \ldots, I_n : T_n) : T \\
& \quad A \vdash \text{add } A \vdash -E_1 : \text{int}; A \vdash -E_2 : \text{int} \\
& \quad A \vdash (+ E_1 E_2) : \text{int} \\
(\text{prepend}) & \quad A \vdash -E_1 : T; A \vdash -E_2 : (\text{listof } T) \\
& \quad A \vdash \text{(prepend } E_1 E_2 : T \\
(\text{head}) & \quad A \vdash -E : (\text{listof } T) \\
& \quad A \vdash \text{(head } E : T \\
(\text{tail}) & \quad A \vdash -E : (\text{listof } T) \\
& \quad A \vdash \text{(tail } E : (\text{listof } T) \\
(\text{empty}) & \quad A \vdash \text{(empty } T) : (\text{listof } T) \\
(\text{empty?}) & \quad A \vdash -E : (\text{listof } T) \\
& \quad A \vdash \text{(empty? } E : \text{bool} \\
\end{align*}
\]

Figure 1: Typing rules for HOFLEMT
As shown above, type derivations can be drawn as trees in which all hypotheses for a rule are on the same line above the horizontal bar and the conclusion of a rule is below the horizontal bar. We shall call this the **horizontal format** for a type derivation.

Using the horizontal format, it is very easy to run out of horizontal space when drawing a type derivation. Below, we illustrate an alternative **vertical format** for displaying the above type derivation that makes much better use of horizontal space:

```
+ (var) A₁ | - f : T₁₁₈
+ (int) A₁ | - 5 : int
+ (app) A₁ | - (f 5) : bool
+ (abs) {} | - (abs ((f T₁₁₈)) (f 5)) : T₁₁₈
+ (var) A₂ | - app5 : T₁₈₈
  + (var) A₃ | - x : int
  + (int) A₃ | - 0 : int
+ (gt) A₃ | - (> x 0) : bool
+ (abs) A₂ | - (abs ((x int)) (> x 0)) : T₁₁₈
+ (app) A₁ | - (app5 E₁₁₈) : bool
  (bind) {} | - (bind app5 E₁₁₈ (app5 E₁₁₈)) : bool
```

In this alternative representation, each conclusion of a rule is labeled with the name of the rule used to derive it, and the hypotheses of the rule are those judgements on the lines labelled “+” directly above the leftmost character of the rule name. Vertical lines are used to connect the hypotheses of the same rule.

Vertical format makes it easier to draw type derivations for more complex expressions using fewer abbreviations without running out of space. For example, Figure 2 shows a type derivation for the following expression:

```
(bindpar ((app5_1 (abs ((f -> (int) int))) (f 5))
  (app5_2 (abs ((f -> (int) -> (int) int)))) (f 5))
(make-sub (abs ((n int)) (abs ((x int)) (- x n))))
(app5_1 (make-sub ((app5_2 make-sub) 3)))
```

The type derivation uses the following abbreviations:

- \( T_{11} = \langle \rightarrow (\text{int}) \text{int} \rangle \)
- \( A₁ = \{ \text{app5}_1 : \langle \rightarrow (T_{11}) \text{int} \rangle, \text{app5}_2 : \langle \rightarrow (\rightarrow (\text{int}) T_{11}) \rangle T_{11}, \text{make-sub} : \langle \rightarrow (\text{int}) T_{11} \rangle \} \)

Note that the above derivation contains two separate copies of the \( \text{app5} \) function: one that assumes the argument \( f \) has type \( \langle \rightarrow (\text{int}) \text{int} \rangle \) and the other that assumes that the argument \( f \) has type \( \langle \rightarrow (\text{int}) \rightarrow (\text{int}) \text{int} \rangle \). Two separate copies of this function are needed in HOFLEMT because it is a monomorphic language: every expression has exactly one type. Since the function is applied at two different argument types, it is necessary to have one copy of the function per argument type.

Examples of real-life monomorphic languages include C, Pascal, and Fortran. As suggested by the above example, in monomorphic languages it may be necessary to create many copies of the same function that differ only in their type. For example, in monomorphic languages, it is necessary to write separate sorting routines for arrays of integers and arrays of floating point numbers because these two arrays have different types! Even worse, in Pascal, the size of the array is part of the array type, so one must write a different sorting function to sort arrays of 10 integers and arrays of 11 integers!
Above we only considered showing that HOFLEMT expressions are well-typed. It is also possible to show that HOFLEMT programs are well-typed. This can be done by showing that the body of the program is well-typed with respect to a type environment where each program parameter is bound to the int type.

3.3 Type Checking

It is possible to check the well-typedness of a HOFLEMT expression or program via an automatic type checker. A type checker is very much like an evaluator, except that rather than finding the type of an expression relative to a value environment, it determines the type of an expression relative to a type environment.

Figures 3 and 4 present an SML implementation of a type checker for HOFLEMT. The core of the type checker is the checkExp function defined in Figure 3, whose SML type is:

```
val checkExp : AST.Exp -> Type Ident.Env.env -> Type
```

The checkExp function encodes all the typing rules from Figure 1 except for the rules that handled primitives. It calculates the type of an expression from the types of its subexpressions. If the subexpression types do not match the typing rules, checkExp raises a TypeCheckError exception indicating that the expression is not well typed.
fun checkExp (Lit(UnitLit)) env = UnitTy
| checkExp (Lit(IntLit(_))) env = IntTy
| checkExp (Lit(BoolLit(_))) env = BoolTy
| checkExp (Lit(StringLit(_))) env = StringTy
| checkExp (Lit(SymLit(_))) env = SymTy

| checkExp (VarRef(name)) env =
  (case TEnv.lookup(name, env) of
   NONE => raise TypeCheckError
     ("Unbound variable: " ^ (Ident.toString(name)))
   | SOME(ty) => ty)
| checkExp (exp as If(test,thenExp,elseExp)) env =
  let val testTy = checkExp test env
  val thenTy = checkExp thenExp env
  val elseTy = checkExp elseExp env
  in if not(Type.equal(testTy,BoolTy)) then
    raise TypeCheckError("if: non-boolean test expression")
  else if not(Type.equal(thenTy,elseTy)) then
    raise TypeCheckError("if: branch types don't match:
      " ^ "Then type: " ^ (Type.toString(thenTy))
      ^ "Else type: " ^ (Type.toString(elseTy)))
  else
    thenTy
  end
| checkExp (Abs(formals,types,body)) env =
  ArrowTy(types, checkExp body (TEnv.extend(formals,types,env)))
| checkExp (FunApp(rator, rands)) env =
  typeApply (checkExp rator env) (checkExpList rands env)
| checkExp (PrimEmpty(ty)) env =
  ListTy(ty) (* special prim in HOFLEMT *)
| checkExp (exp as (PrimApp(primop,rands))) env =
  let val PrimopEnv.PDesc(_,primCheck,_) = PrimopEnv.lookup(primop)
  in primCheck (checkExpList rands env)
  handle PrimopEnv.PrimTypeCheckError(msg) =>
    raise TypeCheckError(msg)
  end
| checkExp(BindPar(names,defns,body)) env =
  checkExp body (TEnv.extend(names, checkExpList defns env, env))
| checkExp (BindRec(names,tys,defns,body)) env =
  let val recEnv = TEnv.extend(names,tys,env)
  val defnTys = checkExpList defns recEnv
  in case ListOps.some3 (fn(name,ty,defnTy) =>
    not (Type.equal(ty,defnTy)))
     names tys defnTys of
      NONE => checkExp body recEnv
      | SOME(name,ty,defnTy) =>
        raise TypeCheckError
          ("bindrec: binding type doesn't match definition type:\n          " ^ "binding name: " ^ (Ident.toString name)
          ^ "\nbinding type: " ^ (Type.toString ty)
          ^ "\ndefinition type: " ^ (Type.toString defnTy))
      end
    end

and checkExpList exps env = map (fn exp => checkExp exp env) exps

    | SOME(fty,aty) =>
      raise TypeCheckError
      ("funapp: formal type doesn't match actual type.\n" ^ "Expected: " ^ (Type.toString fty) ^ 
        "Actual: " ^ (Type.toString aty))
    )
    | typeApply ratorTy _ = raise TypeCheckError
      ("funapp: attempt to apply non function --\n" ^ "Rator type: " ^ (Type.toString ratorTy))
  )

end (* local *)
end (* struct *)

Figure 4: SML definition of HOFLEMT type checker.
The type checking of primitive applications is specified in the PrimopEnv structure (not shown in the figures). This module has the following signature:

```sml
signature PRIMOP_ENV = sig

  exception PrimTypeCheckError of string
  exception PrimEvalError of string

  datatype PrimDesc =
    PDesc of   Primitive.Primop              (* name of primitive *)
    * (Type.Ty list -> Type.Ty)     (* type checker *)
    * (Value.Val list -> Value.Val) (* meaning of primop *)

  val lookup : Primitive.Primop -> PrimDesc

end
```

The `PrimDesc` datatype is used to encode the type checking rules and evaluation rules of primitive operators. Figure 5 shows a few representative examples of the primitive descriptors for HOFLEMT. The `typeMismatch` function (not shown) raises a `PrimTypeError` exception with an appropriate explanation of the mismatch.

The type of a program is found by the `checkProg` function in Figure 4, whose SML type is:

```sml
val checkProg : AST.Program -> Type
```

The `checkProg` function returns the type of the body of a program under the assumption that all the arguments of the program are integers. Like `checkExp`, it raises a `TypeCheckError` exception if the program is not well-typed.
