

x86 Control Flow

(Part A, Part B)

Condition codes, comparisons, and tests
[Un]Conditional jumps and conditional moves
Translating if-else, loops, and switch statements

Motivation

Recall: instruction memory is a flat list (with the program counter as index)!

We don't get to keep

`if/while/for/break/continue`

Conditionals and Control Flow

Two key pieces

1. Comparisons and tests: check conditions
2. Transfer control: choose next instruction

To implement familiar C constructs

- if else
- while
- do while
- for
- break
- continue

Processor Control-Flow State

Condition codes (a.k.a. *flags*)

1-bit registers hold flags set by last ALU operation

- ZF** Zero Flag result == 0
- SF** Sign Flag result < 0
- CF** Carry Flag carry-out/unsigned overflow
- OF** Overflow Flag two's complement overflow

`%rip` **Instruction pointer**
(a.k.a. *program counter*)
register holds address of next instruction to execute

1. Compare and test: conditions

`cmpq b, a` computes $a - b$, sets flags, discards result

Which flags indicate that $a < b$? (signed? unsigned?)

`testq b, a` computes $a \& b$, sets flags, discards result

Common pattern:

`testq %rax, %rax`

What do ZF and SF indicate?

2. Transfer control: choose next instruction

Different **jump/branch instructions** to different part of code by setting `%rip`.

	j_	Condition	Description
Unconditional jump	<code>jmp</code>	<code>1</code>	Unconditional
	<code>je</code>	<code>ZF</code>	Equal / Zero
	<code>jne</code>	<code>~ZF</code>	Not Equal / Not Zero
Conditional jumps	<code>js</code>	<code>SF</code>	Negative
	<code>jns</code>	<code>~SF</code>	Nonnegative
	<code>jg</code>	<code>~(SF^OF) & ~ZF</code>	Greater (Signed)
	<code>jge</code>	<code>~(SF^OF)</code>	Greater or Equal (Signed)
	<code>jle</code>	<code>(SF^OF) ZF</code>	Less or Equal (Signed)
	<code>jnl</code>	<code>(SF^OF)</code>	Less (Signed)
	<code>jle</code>	<code>(SF^OF) ZF</code>	Less or Equal (Signed)
	<code>ja</code>	<code>~CF & ~ZF</code>	Above (unsigned)
	<code>jb</code>	<code>CF</code>	Below (unsigned)

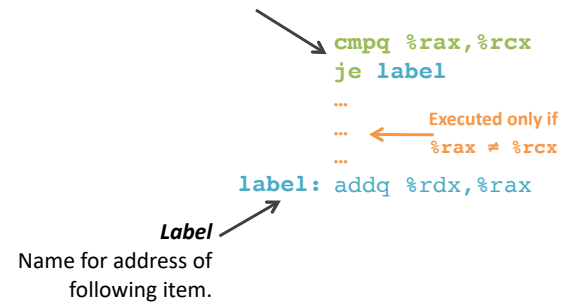

5

Jump for control flow

Jump immediately follows comparison/test.

Together, they make a decision:

"if `%rcx == %rax` then jump to label."

6

Interpreting Conditional Jumps

It is easier to read conditional jumps in x86-64 by comparing `b` against `a` instead of looking at condition codes.

		<code>cmp b,a</code>	<code>test b,a</code>
<code>je</code>	"Equal"	<code>a == b</code>	<code>a&b == 0</code>
<code>jne</code>	"Not equal"	<code>a != b</code>	<code>a&b != 0</code>
<code>js</code>	"Sign" (negative)	<code>a < b < 0</code>	<code>a&b < 0</code>
<code>jns</code>	(non-negative)	<code>a - b >= 0</code>	<code>a&b >= 0</code>
<code>jg</code>	"Greater"	<code>a > b</code>	<code>a&b > 0</code>
<code>jge</code>	"Greater or equal"	<code>a >= b</code>	<code>a&b >= 0</code>
<code>jle</code>	"Less or equal"	<code>a <= b</code>	<code>a&b <= 0</code>
<code>ja</code>	"Above" (unsigned >)	<code>a > b</code>	<code>a&b > 0U</code>
<code>jb</code>	"Below" (unsigned <)	<code>a < b</code>	<code>a&b < 0U</code>

Instruction	Condition
<code>cmpq 5, (p)</code>	
<code>je: *p == 5</code>	<code>*p == 5</code>
<code>jne: *p != 5</code>	<code>*p != 5</code>
<code>jg: *p > 5</code>	<code>*p > 5</code>
<code>jle: *p < 5</code>	<code>*p < 5</code>

Instruction	Condition
<code>testq a, a</code>	
<code>je: a == 0</code>	<code>a == 0</code>
<code>jne: a != 0</code>	<code>a != 0</code>
<code>jg: a > 0</code>	<code>a > 0</code>
<code>jle: a < 0</code>	<code>a < 0</code>

7

Conditional branch example

```

long absdiff(long x, long y) {
    long result;
    if (x > y) {
        result = x - y;
    } else {
        result = y - x;
    }
    return result;
}
    
```

How did the compiler create this?

8

Control-Flow Graph

Code flowchart/directed graph.

Introduced by Fran Allen, et al.
 Won the 2006 Turing Award
 for her work on compilers.

Nodes = **Basic Blocks**:
 Straight-line code always
 executed together in order.

```
long absdiff(long x, long y){
    long result;
    if (x > y) {
        result = x-y;
    } else {
        result = y-x;
    }
    return result;
}
```

Edges = **Control Flow**:
 Which basic block executes
 next (under what condition).

Control-Flow Graph

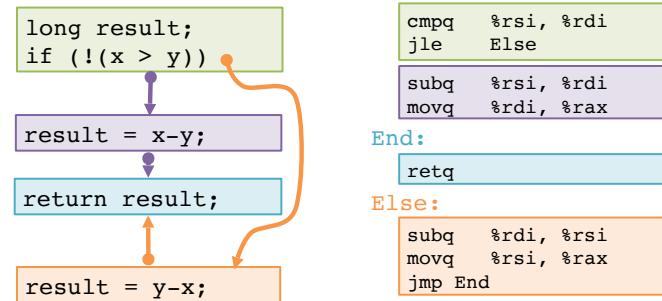

How do we represent this non-flat structure in a single instruction memory?

Choose a linear order of basic blocks.

Translate basic blocks with jumps + labels

Execute absdiff

```
cmpq %rsi, %rdi  
jle Else
```

```
subq %rsi, %rdi  
movq %rdi, %rax
```

End:

```
retq
```

Else:

```
subq %rdi, %rsi  
movq %rsi, %rax  
jmp End
```

Registers

%rax	
%rdi	5
%rsi	3

ex

13

Execute absdiff

```
cmpq %rsi, %rdi  
jle Else
```

```
subq %rsi, %rdi  
movq %rdi, %rax
```

End:

```
retq
```

Else:

```
subq %rdi, %rsi  
movq %rsi, %rax  
jmp End
```

Registers

Else:

```
subq %rdi, %rsi
movq %rsi, %rax
jmp End
```

Registers

%rax	3
%rdi	4
%rsi	7 3

ex

18

Note: CSAPP shows translation with goto

```
long absdiff(long x, long y){
    int result;
    if (x > y) {
        result = x-y;
    } else {
        result = y-x;
    }
    return result;
}
```

```
long goto_ad(long x, long y){
    int result;
    if (x <= y) goto Else;
    result = x-y;
End:
    return result;
Else:
    result = y-x;
    goto End;
}
```

19

But never use goto in your source code!

<http://xkcd.com/292/>

20

Compile if-else

ex

```
long wacky(long x, long y){
    long result;
    if (x + y > 7) {
        result = x;
    } else {
        result = y + 2;
    }
    return result;
}
```

Assume x is available in %rdi,
y is available in %rsi.

Place result in %rax for return.

wacky:

21

Compile if-else (solution #1)

ex

```
long wacky(long x, long y){
    long result;
    if (x + y > 7) {
        result = x;
    } else {
        result = y + 2;
    }
    return result;
}
```

Assume x is available in %rdi,
y is available in %rsi.

Place result in %rax for return.

```
wacky:
    movq %rdi, %rdx
    addq %rsi, %rdx
    cmpq $7, %rdx
    jle Else

    movq %rdi, %rax
```

End:
retq

Else:
addq \$2, %rsi
movq %rsi, %rax
jmp End

22

Compile if-else (solution #2)

ex

```
long wacky(long x, long y){
    long result;
    if (x + y > 7) {
        result = x;
    } else {
        result = y + 2;
    }
    return result;
}
```

Assume x is available in %rdi,
y is available in %rsi.

Place result in %rax for return.

```
wacky:
    leaq (%rdi, %rsi), %rdx
    cmpq $7, %rdx
    jle Else

    movq %rdi, %rax

End:
retq

Else:
leaq 2(%rsi), %rax
jmp End
```

23

Encoding jumps: PC-relative addressing

0x100	cmpq %rax, %rbx	0x1000
0x102	je 0x70	0x1002
0x104	...	0x1004
...
0x174	addq %rax, %rbx	0x1074

↓

PC-relative *offsets* support relocatable code.
Absolute branches do not (or it's hard).

24

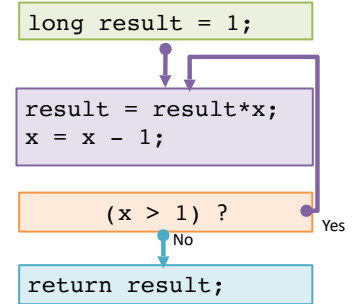

x86 Control Flow

(Part A, Part B)

Condition codes, comparisons, and tests
[Un]Conditional jumps and **conditional moves**
Translating if-else, loops, and switch statements

do while loop

```
long fact_do(long x) {
  // Assume x >= 1
  long result = 1;
  do {
    result = result * x;
    x = x - 1;
  } while (x > 1);
  return result;
}
```

do while loop

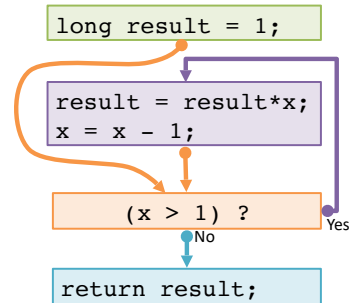

```
fact_do:
  movq $1,%rax
.L11:
  imulq %rdi,%rax
  decq %rdi
  cmpq $1,%rdi
  jg .L11
  retq
```

Why put the loop condition at the end?

while loop

```
long fact_while(long x){
  // Assume >= 0
  long result = 1;
  while (x > 1) {
    result = result * x;
    x = x - 1;
  }
  return result;
}
```

This order is used by GCC for x86-64. Why?

while loop

```
long fact_while(long x){
// Assume x >= 0
long result = 1;
while (x > 1) {
    result = result * x;
    x = x - 1;
}
return result;
}
```

```
int result = 1;
```

```
result = result * x;
x = x - 1;
```

```
(x > 1) ?
```

```
return result;
```

fact_while:

```
movq $1, %rax
jmp .L34
```

```
.L35:
imulq %rdi, %rax
decq %rdi
```

```
.L34:
cmpq $1, %rdi
jg .L35
```

```
retq
```

29

for loop translation

for loops are syntactic sugar for while loops: we can just translate for to while

```
for (Initialize; Test; Update) {
    Body
}
```

```
Initialize;
while (Test) {
    Body;
    Update;
}
```

```
for (result = 1; p != 0; p = p>>1) {
    if (p & 0x1) {
        result = result * x;
    }
    x = x * x;
}
```

30

for loop: square-and-multiply

optional

```
/* Compute x raised to nonnegative power p */
int power(int x, unsigned int p) {
    int result;
    for (result = 1; p != 0; p = p>>1) {
        if (p & 0x1) {
            result = result * x;
        }
        x = x*x;
    }
    return result;
}
```

$x^m * x^n = x^{m+n}$

0 ... 0 1 0 1 1 = 11
 $1^{2^3} * \dots * 1^{16} * x^8 * 1^4 * x^2 * x^1 = x^{11}$
 $1 = x^0 \quad x = x^1$

Algorithm

Exploit bit representation: $p = p_0 + 2p_1 + 2^2p_2 + \dots + 2^{n-1}p_{n-1}$

Gives: $x^p = z_0 \cdot z_1 \cdot z_2 \cdot \dots \cdot \underbrace{((z_{n-1})^2) \dots)^2}_{n-1 \text{ times}}$

$z_i = 1$ when $p_i = 0$

$z_i = x$ when $p_i = 1$

Complexity $O(\log p) = O(\text{sizeof}(p))$

Example

$3^{11} = 3^1 * 3^2 * 3^8$
 $= 3^1 * 3^2 * ((3^2)^2)^2$

31

for loop: power iterations

optional

```
/* Compute x raised to nonnegative power p */
int power(int x, unsigned int p) {
    int result;
    for (result = 1; p != 0; p = p>>1) {
        if (p & 0x1) {
            result = result * x;
        }
        x = x*x;
    }
    return result;
}
```

iteration	result	x	p
0	1	3	11 = 1011 ₂
1	3	9	5 = 101 ₂
2	27	81	2 = 10 ₂
3	27	6561	1 = 1 ₂
4	177147	430467	0 ₂

32

(Aside) Conditional Move

cmov_src, dest
if (**Test**) **Dest** ← **Src**

```
long absdiff(long x, long y) {
    return x>y ? x-y : y-x;
}
```

```
absdiff:
    movq    %rdi, %rax
    subq   %rsi, %rax
    movq   %rsi, %rdx
    subq   %rdi, %rdx
    cmpq   %rsi, %rdi
    cmovle %rdx, %rax
    ret
```

```
long absdiff(long x, long y) {
    long result;
    if (x > y) {
        result = x - y;
    } else {
        result = y - x;
    }
    return result;
}
```

Why? Branch prediction in pipelined/OoO processors.

33

(Aside) Bad uses of conditional move

Expensive Computations

```
val = Test(x) ? Hard1(x) : Hard2(x);
```

Risky Computations

```
val = p ? *p : 0;
```

Computations with side effects

```
val = x > 0 ? x++ : x--;
```

34

switch statement

```
long switch_eg (long x, long y, long z) {
    long w = 1;
    switch(x) {
    case 1:
        w = y * z;
        break;
    case 2:
        w = y - z;
    case 3:
        w += z;
        break;
    case 5:
    case 6:
        w -= z;
        break;
    default:
        w = 2;
    }
    return w;
}
```

Fall through cases

Multiple case labels

Missing cases use default

Lots to manage:
use a **jump table**.

35

switch jump table structure

C code:

```
switch(x) {
    case 1: <some code>
        break;
    case 2: <some code>
        break;
    case 3: <some code>
        break;
    case 5:
    case 6: <some code>
        break;
    default: <some code>
}
```

Translation sketch:

```
if (0 <= x && x <= 6)
    addr = jumptable[x];
goto addr;
else
    goto default;
```

36

switch jump table assembly declaration

```

read-only data
(not instructions)
.section .rodata
.align 8
.L4:
.quad .L8 # x == 0
.quad .L3 # x == 1
.quad .L5 # x == 2
.quad .L9 # x == 3
.quad .L8 # x == 4
.quad .L7 # x == 5
.quad .L7 # x == 6

switch(x) {
case 1: // .L3
    w = y * z;
    break;
case 2: // .L5
    w = y - z;
case 3: // .L9
    w += z;
    break;
case 5: // .L7
case 6: // .L7
    w -= z;
    break;
default: // .L8
    w = 2;
}
    
```

Annotations: "quad" = q suffix = 8-byte value; 8-byte alignment; read-only data (not instructions).

switch case dispatch

```

long switch_eg(long x, long y, long z) {
    long w = 1;
    switch(x) {
        . . .
    }
    return w;
}

switch_eg:
    movl $1, %eax
    cmpq $6, %rdi
    ja .L8
    jmp *.L4(,%rdi,8)

Jump if above (unsigned, but...)
indirect jump
    
```

Jump table:

```

.section .rodata
.align 8
.L4:
.quad .L8 # x == 0
.quad .L3 # x == 1
.quad .L5 # x == 2
.quad .L9 # x == 3
.quad .L8 # x == 4
.quad .L7 # x == 5
.quad .L7 # x == 6
    
```

switch cases

<pre> switch(x) { case 1: // .L3 w = y * z; break; case 2: // .L5 w = y - z; case 3: // .L9 w += z; break; case 5: // .L7 case 6: // .L7 w -= z; break; default: // .L8 w = 2; } return w; </pre>	<pre> .L3: movq %rsi, %rax imulq %rdx, %rax retq ← "inlined" return .L5: movq %rsi, %rax subq %rdx, %rax .L9: ← Fall-through addq %rdx, %rax retq .L7: subq %rdx, %rax retq .L8: movl \$2, %eax retq </pre>	<table border="1"> <thead> <tr> <th>Reg.</th> <th>Use</th> </tr> </thead> <tbody> <tr> <td>%rdi</td> <td>x</td> </tr> <tr> <td>%rsi</td> <td>y</td> </tr> <tr> <td>%rdx</td> <td>z</td> </tr> <tr> <td>%rax</td> <td>w</td> </tr> </tbody> </table>	Reg.	Use	%rdi	x	%rsi	y	%rdx	z	%rax	w
Reg.	Use											
%rdi	x											
%rsi	y											
%rdx	z											
%rax	w											

Aside: movl is used because 2 is a small positive value that fits in 32 bits. High order bits of %rax get set to zero automatically. It takes fewer bytes to encode a literal movl vs a movq.

switch machine code

```

switch_eg:
    . . .
    cmpq $6, %rdi
    ja .L8
    jmp *.L4(,%rdi,8)
    
```

Disassembled Object Code:

```

00000000004004f6 <switch_eg>:
    . . .
    4004fd: 77 2b                ja 40052a <switch_eg+0x34>
    4004ff: ff 24 fd d0 05 40 00 jmpq *0x4005d0(,%rdi,8)
    
```

Inspect jump table contents using GDB.

Examine contents as 7 addresses

```

(gdb) x/7a 0x4005d0
0x4005d0: 0x40052a <switch_eg+52> 0x400506 <switch_eg+16>
0x4005e0: 0x40050e <switch_eg+24> 0x400518 <switch_eg+34>
0x4005f0: 0x40052a <switch_eg+52> 0x400521 <switch_eg+43>
0x400600: 0x400521 <switch_eg+43>
    
```

Annotations: Address of code for case 0; Address of code for case 1; Address of code for case 6.

When looking as disassembled code: an indirect jump like this is a sign it's a jump table encoding a switch

Would you implement this with a jump table?

ex

```
switch(x) {  
  case 0:    <some code>  
            break;  
  case 10:   <some code>  
            break;  
  case 52000: <some code>  
            break;  
  default:  <some code>  
            break;  
}
```
