

You Can Do More If You're Lazy!

Handout #40

CS251 Lecture 34

April 23, 2002

A Modularity Problem

Consider infinite sequences of integers, such as:

- powers of 2: 1, 2, 4, 8, 16, 32, 64, ...
- factorials: 1, 1, 2, 6, 24, 120, 720, ...
- Fibonacci numbers: 0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, ...
- primes: 2, 3, 5, 7, 11, 13, 17, 19, 23, 29 ...

Suppose we want answers to questions like the following:

- What are the first n elements?
- What is the first element greater than 100?
- What is the (0-based) index of the first element greater than 100?
- What is the first consecutive pair whose difference is more than 25?
- For which index i is the sum of elements 0 through i more than 1000?

Challenge: can we answer these questions in a modular way?

Non-Modular Haskell Solutions

```
fibPrefix :: Integer -> [Integer]
fibPrefix num = gen 0 0 1
  where gen n a b =
        if n >= num then []
        else a : (gen (n + 1) b (a + b))

leastFibGt :: Integer -> Integer
leastFibGt lim = least 0 1
  where least a b = if a > lim then a
                    else least b (a + b))

fibSumIndex :: Integer -> Integer
fibSumIndex lim = index 0 0 0 1
  where index i sum a b =
        if sum > lim then i
        else index (i+1) (sum+a) b (a + b)
```

A More Modular Approach: Infinite Lists

Idea: Separate the generation of the sequence elements from subsequent processing. Since we don't know how many elements we'll need, generate *all* of them -- *lazily!*

```
nats = genNats 0 where genNats n = n : genNats (n + 1)
-- Can also be written: nats = [0..]

poss = tail nats -- the positive integers
-- Can also be written: poss = [1..]

powers n = genPowers 1
  where genPowers x = x : (genPowers (n * x))

facts = genFacts 1 1
  where genFacts ans n = ans : (genFacts (n*ans) (n + 1))

fibs = genFibs 0 1
  where genFibs a b = a : (genFibs b (a + b))
```

Processing Infinite Lists

Note: We assume the following functions are invoked only on infinite lists. This allows us to ignore the empty list as a base case! Each function *can* be extended to handle the empty list as well.

```
-- Returns a list of the first n elements of a given list.
take n (x:xs) = if (n == 0) then [] else x : (take (n-1) xs)

-- Returns first element satisfying predicate p
firstElem p (x:xs) = if (p x) then x else firstElem p xs

-- Returns first contiguous pair satisfying predicate p
firstPair p (x:y:zs) =
  if (p(x,y)) then (x,y) else firstPair p (y:zs)

-- Returns (0-based) index of first elt satisfying pred p
index p xs = ind 0 xs
  where ind i (x : xs) =
    if (p x) then i else (ind (i+1) xs)
```

Examples

```
take 10 fibs
```

```
firstElem (\ x -> x > 100) (powers 2)
```

```
index (\ x -> x > 1000) facts
```

```
firstPair (\(x,y) -> (y - x) > 25) fibs
```

Scanning

Scanning accumulates the partial results of a `foldl` into a list.

```
scanl :: (a -> b -> a) -> a -> [b] -> [a]
```

```
scanl f ans (x:xs) = ans : scanl f (f ans x) xs)
```

```
scanl (+) 0 (powers 2) -- be careful of initial zero!
```

```
-- alternative definition of facts
```

```
facts = scanl (*) 1 ints
```

```
-- Like scanl, but uses first elt as initial answer
```

```
scanl1 :: (a -> a -> a) -> [a] -> [a]
```

```
scanl1 f (x:xs) = scanl f x xs
```

```
index (fn s -> s > 1000) (scanl1 (+) 0 fibs)
```

Higher-order Generation of Infinite Sequences

```
iterate :: (a -> a) -> a -> [a]
```

```
iterate f x = x : iterate f (f x)
```

```
-- another way to generate the nats
```

```
nats = iterate (1 +) 0
```

```
iterate2 :: (a -> a -> a) -> a -> a -> [a]
```

```
iterate2 f x1 x2 = x1 : iterate2 f x2 (f x1 x2)
```

```
-- another way to generate the fibs
```

```
fibs = iterate2 (+) 0 1
```

```
iteratei :: (Integer -> a -> a) -> Integer -> a -> [a]
```

```
iteratei f n x = x : iteratei f (n + 1) (f n x)
```

```
-- a third way to generate the facts
```

```
facts = iteratei (*) 1 1
```

Cyclic Definitions of Infinite Sequences

```
ones = 1 : ones
```

```
-- a third way to generate the nats
```

```
nats = 0 : (map (1 +) nats)
```

```
zipWith :: (a -> b -> c) -> [a] -> [b] -> [c]
```

```
zipWith f (x:xs) (y:ys) = (f x y) : (zipWith f xs ys)
```

```
-- a fourth way to generate the nats
```

```
nats = 0 : (zipWith (+) ones nats)
```

```
-- a fourth way to generate the facts
```

```
facts = 1 : (zipWith (*) poss facts)
```

```
-- a third way to generate the fibs
```

```
fibs = 0 : 1 : (zipWith (+) fibs (tail fibs))
```

Generating Primes

Idea: use the “sieve of Eratosthenes”

```
sieve (x:xs) =  
  x : (sieve (filter (\ y -> (rem y x) /= 0) xs))  
  
primes = sieve (tail (tail nats)) -- start sieving at 2
```

Not only does this give an *infinite* list of primes, it does so *efficiently* by avoiding unnecessary divisions.

For more examples of lazy lists in Haskell, see Chapter 17 of Simon Thompson’s book *Haskell: The Craft of Functional Programming*.

Lazy Trees

Can use laziness to perform a two-pass tree walk in a single pass:

```
data Tree a = Leaf | Node (Tree a) a (Tree a)

addMax tr = tr'
  where (tr', m) = walk tr
        walk Leaf = (Leaf, 0)
        walk (Node l v r) = (Node l' (m + v) r',
                              max3 ml v mr)
          where (l', ml) = walk l
                (r', mr) = walk r

max3 a b c = max a (max b c)
```

See Hughes's paper "*Why Functional Programming Matters*" for compelling lazy game tree example.

Streams : Lazy Lists for Scheme

`(cons-stream Ehead Etail)`

Return a (potentially infinite) stream whose head is the value of *Ehead* and whose tail is the value of *Etail*. The evaluation of *Etail* is delayed until it is needed.

`(head Estream)`

Return the head element of the stream value of *Estream*.

`(tail Estream)`

Return the tail of the stream value of *Estream*. This forces the computation of the delayed tail expression.

`(stream-null? Estream)`

Return `true` if *Estream* is the empty stream and `false` otherwise.

`the-empty-stream`

The empty stream

Stream Examples I

```
(define ints-from
  (lambda (n)
    (cons-stream n (ints-from (+ n 1))))) ; No base case!
```

;; Converts first n elements of infinite stream to a list

```
(define take
  (lambda (n str)
    (if (= n 0)
        '()
        (cons (head str) (take (- n 1) (tail str))))))
```

```
(define ones (cons-stream 1 ones))
```

```
(define map-stream
  (lambda (f str)
    (cons-stream (f (head str))
                 (map-stream f (tail str)))))
```

```
(define nats (cons-stream 0 (map-stream (lambda (x) (+ x 1)) nats)))
```

Stream Examples II

```
(define map2-streams
  (lambda (f str1 str2)
    (cons-stream (f (head str1) (head str2))
                  (map2-streams f (tail str1) (tail str2))))))
```

```
(define fibs
  (cons-stream 0
              (cons-stream 1
                            (map2-streams + fibs (tail fibs)))))
```

- Can similarly translate other lazy list examples from Haskell to Scheme
- See Section 3.5 of *SICP* for lots of examples.

Implementing Lazy Data in a Strict Language

- *Idea* -- use memoizing promises to implement lazy lists in Scheme:

```
(cons-stream E1 E2) is syntactic sugar for (cons E1 (delay E2))
```

```
(define (head s) (car s))
```

```
(define (tail s) (force (cdr s)))
```

```
(define (null-stream? s) (null? s))
```

```
(define the-empty-stream '())
```

- Can generalize this idea to handle infinite trees.
- Can similarly implement lazy lists in ML.
- Lazy data is very helpful, but sometimes need even more laziness (e.g. translating `addMax` example to Scheme or ML).

Java Enumerations

Like streams, Java's enumerations can be conceptually infinite. For example:

```
public class FibEmumeration implements Enumeration {  
    private int a, b;  
    public FibEnumeration () { a = 0; b = 1; }  
    public boolean hasMoreElements () { return true; }  
    public Object nextElement () {  
        int old_a = a;  
        a = b;  
        b = old_a + b;  
        return new Integer(old_a);  
        // Convert int to Integer to satisfy type of nextElement  
    }  
}
```

- Unlike streams, enumerations are not *persistent*; can't hold on to a snapshot of the enumeration at given point in time without copying it.
- While lazy data is easy to adapt to trees, enumerations are inherently linear.
